Aim: To implement the concept of single inheritance.

Objective: Ability to design a base and child class relationship to increase reusability.

Theory:

Single inheritance can be defined as a derived class to inherit the basic methods (data members and variables) and behaviour from a superclass. It's a basic is-a relationship concept exists here. Basically, java only uses a single inheritance as a subclass cannot extend more superclass.

Inheritance is the basic properties of object-oriented programming. Inheritance tends to make use of the properties of a class object into another object. Java uses inheritance for the purpose of code-reusability to reduce time by then enhancing reliability and to achieve run time polymorphism. As the codes are reused it makes less development cost and maintenance. Java has different types of inheritance namely single inheritance, multilevel, multiple, hybrid. In this article, we shall go through on basic understanding of single inheritance concept briefly in java with a programming example. Here we shall have a complete implementation in java.

Syntax:

The general syntax for this is given below. The inheritance concepts use the keyword 'extend' to inherit a specific class. Here you will learn how to make use of extending keyword to derive a class. An extend keyword is declared after the class name followed by another class name. Syntax is,

```
class base class
```

```
{.... methods
```

```
}
```

```
class derived class name extends base class
```

```
{
```

methods ... along with this additional feature

```
}
```

Java uses a keyword 'extends' to make a new class that is derived from the existing class. The inherited class is termed as a base class or superclass, and the newly created class is called derived or subclass. The class which gives data members and methods known as the base class and the class which takes the methods is known as child class.

Code:

```
class singleInheritance{

    public static void main(String args[])

    {

        Dog d = new Dog();

        d.eat();

        d.bark();

    }

}

class Animal

{

    void eat()

    {

        System.out.println("the animal is eating");

    }

}
```

```
}
```

```
class Dog extends Animal
```

```
{
```

```
    void bark()
```

```
    {
```

```
        System.out.println("the animal is barking");
```

```
    }
```

```
}
```

Output:

```
C:\Users\student\Desktop\jdk-17\bin>javac SingleInheritance.java

C:\Users\student\Desktop\jdk-17\bin>java SingleInheritance.java
the animal is eating
the animal is barking

C:\Users\student\Desktop\jdk-17\bin>
```

Conclusion:

Single inheritance in Java is a mechanism in which a class can inherit the properties and methods of a single parent class. This is in contrast to multiple inheritance, where a class can inherit the properties and methods of multiple parent classes.

Single inheritance is supported in Java because it is considered to be a simpler and more maintainable model of inheritance. Multiple inheritance can lead to complex and difficult-to-understand code, especially when there are conflicts between the methods of the parent classes.
